

Entrusting Protocol Design: problem settlement, requirements and related protocols

Vasily Desnitsky

**Computer Security Research Group,
St. Petersburg Institute for Informatics and
Automation of Russian Academy of Sciences**

Protocols Investigation

- Problem settlement
- Determination of possible Attacks and related protocol requirement
- Analysis of requirements to Entrusting Protocol
- Proposals to Entrusting Protocol
- Entrusting Protocol Resistance analysis
- Getting of estimations of attack time complexity for dynamic replacement mechanism support

**Current
work**

Reference Architecture

Transmitted Data

- Entrusting Tags
 - Small data portion
 - Continuous dataflow and even in time
- SW Module code
 - Occasional data sending
- Challenge from Trusted Server to Client
 - Occasional data sending
- Additional services, update, maintenance
 - Use their own protection mechanisms

Attacks

Eavesdropping of Tags for its analysis

**Eavesdropping of SW module to get its code
for malicious usage or for its analysis**

**Tag or SW Module interception
and its modification**

Tags Replay attack

Interleaving attack

Impersonation attack

Tag dataflow blocking

Attacks and Entrusting Protocol requirements

Attacks

Eavesdropping of Tags for its analysis

Eavesdropping of SW module to get its code for malicious usage or for its analysis

Tag or SW Module interception and its modification

Tags Replay attack

Interleaving attack

Impersonation attack

Tag dataflow blocking

Protocol Requirements

Confidentiality of transmitted data

Data authentication and integrity

Timeliness of data delivery

Server authentication

Identification of clients

- Trusted Server needs to distinguish different clients
- To identify each running copy of the program being protected on the client
- Identification by IP address
 - Constraint: it's applicable for local area network only where IP can unambiguously determine each client
- Artificial unique identifier supplied by Trusted Server
 - Getting a new identifier after every new program start
 - No need to protect identifier

Approach to Server Authentication

- Client should have guarantee he is communicating with real Trusted Server
- The way is to find
 - some property inherent Trusted Server
 - some secret data, the secrecy meaning certain *hard computational problem*
- To construct a *knowledge proof protocol* demonstrating ownership of the secret to client
- Open question: how to discover such secret?

Confidentiality

- Guarantee of impossibility of data decoding by a malicious user
- Symmetric key schemes
 - (+) High time rate
 - Possible for implementation of Entrusting Tags, SW Module and Challenge encryption/decryption
 - (-) Necessity of secure secret key management
 - *E.g. 3DES, IDEA, AES in CBC mode*
- Public key cryptography schemes
 - (-) Low time rate
 - Possible for Entrusting Tags and Challenge
 - (-) Necessity of guarantee of public key authenticity by a specific certificating entity
 - *E.g. RSA*
- Hybrid cryptosystems
 - Combination of symmetric and public key encryption
 - Possible for Entrusting Tags, SW Module and Challenge

Data Authentication and Integrity

- To be able to determine if this subject is the author of given data
- To prevent a malicious user to forge or modify transmitted data
- Data authentication assumes data integrity
- Message Authentication Codes (MAC) for symmetric schemes
 - Use hash-function based on shared secret key
- Digital signature for public key schemes
- Encrypt-then-authenticate
- Authenticated encryption
- Digital signature schemes giving message recovery

Timeliness

- Requires to deliver Entrusting Tags and SW Module in specific time
- To verify the tag was generated and sent no later than certain time instant
- 1 strategy: validity window determination
 - Forced delays in Tag Generation and Delivery Process
 - Network characteristics (determination be specific request to client)
 - SW Module characteristics (e.g. verification function amount)
 - Program being protected characteristics (e.g. program's size, memory volume in use, etc.)
 - characteristics of client's HW resources and OS
- 2 strategy: to tie information to its creation time instant
 - Algorithm of tag creation should depend on time
 - Capability to check creation time of Tags

Message loss

- In case of one message loss Trusted Server immediately start to consider client program as tampered
- Possible means
 - Superfluity – information doubling
 - Server reaction – request to Client to repeat the message
 - Low layer protocol support

Protocol Design Issues

- Need of protection on Network layer
- Suggestion
 - To implement Entrusting Protocol as Application layer protocol over secure network layer protocol
- Two proposals:
 - Internet Security Protocol (IPSec)
 - Secure Sockets Layer (SSL)

IPSec Protocol

- Network layer protocol providing
 - Data Authentication and integrity
 - Secrecy (confidentiality) – encryption of IP-packets
 - Replay attack prevention
- Authentication Header protocol (AH)
- Encapsulating Security Payload protocol (ESP)
- Internet Key Exchange Protocol (IKE)
- IP Payload Compression Protocol (IPComp)
- Transport and Tunnel modes

Data Authentication and Confidentiality in IPSec

- Authentication Header
 - Security Parameter Index (SPI)
 - Authentication Code
 - Sequence Number
- Encapsulating Security Payload
 - SPI
 - Sequence Number
 - Payload
 - Authentication Code
- Internet Key Exchange Protocol (IKE)
 - To agree cryptographic algorithms and shared secret keys
 - Modification of keys during protocol act

Application of IPSec to Entrusting Protocol (1/2)

- Combination of AH and ESP for IP-packet protection
 - AH – integrity and authentication of IP packet including IP header
 - ESP – IP packet payload confidentiality
- Transport mode use
- AH doesn't protect mutable fields from IP header
- IPSec doesn't depend on concrete cryptographic algorithms in use. It allows to add new cryptographic algorithms when they appear

Application of IPSec to Entrusting Protocol (2/2)

Approach to Resistance Analysis of IPSec based proposal

- AH and ESP headers contain Transforms, that hide all cryptographic concerns
- Resistance of AH and ESP against attacks in the first place means resistance of cryptographic algorithms in use
- IKE protocol is very tangled and hard to analyze
 - In contrast to AH and ESP all cryptographic concerns are implemented within IKE

Secure Sockets Layer Protocol (SSL)

- SSL provide
 - Integrity
 - Data authentication
 - Confidentiality
- SSL is implemented within Transport Layer protocol
- Two levels of SSL:
 - SSL Handshake Protocol – allows to agree cryptographic algorithms and keys
 - SSL Record Protocol – provide secure encapsulation of implemented high layer protocol (e.g. HTTP, LDAP, IMAP)

Application of SSL to Entrusting Protocol

- SSL is compatible with all contemporary proxy servers and routers
- Use of cipher block chaining (CBC) for data encryption
- Possibility of change of encryption specification during protocol fulfillment (protocol of cipher specification modification)

Future work

- Analysis of Entrusting Protocol Resistance
- Analysis of attacks on Entrusting Protocol
- Getting of estimations of attack time complexity for dynamic replacement mechanism support
